Abstract

Algebra of projective differential invariants and description of projective classes of regular smooth plane curves are found. A classification and projective normal forms for special classes of plane curves are given.

Key words: plane curve, W-curve, elliptic curve, projective differential invariant, projective curvature, Study differential

2010 Mathematics subject classification: 53A20 53A55

1. Introduction

In this paper we investigate projective equivalence of smooth curves on the real projective plane. Some of these results are classical and known. Mainly they go back to Halphen's dissertation ([2]).

The considered curves are smooth but they have singularities in projective sense. For example, singular, from the projective point of view, are points on a curve, where tangent line has second order contact, i.e. inflection or flex points. Another example gives points on a curve, where osculating quadric has 5-th order contact, i.e. Monge points.
We describe $\text{SL}_3(\mathbb{R})$-orbits of the projective action on jets of smooth plane curves up to 5-th order and classify all possible projective singularities. The level of 5-th jets taken for the only reason: starting from 6-jets regular orbits have trivial stabilizers, and from the level of 7-jets first differential invariants come up. This orbit classification gives projective classification, or projective normal forms for smooth curves, up to 6-th order jets.

To find the complete algebra of differential invariants we reproduce the Study derivation in suitable for us form. It allows us to prove that algebra of polynomial differential invariants which separates regular orbits can be obtained from the projective curvature by taking of higher Study derivatives (Theorem 4). As a by-product of this theorem we get two results: normal forms curves up to 10-th jets (Theorem 6) and projective classification of germs regular smooth curves (Theorem 5).

The rest of the paper devoted to special classes of plane curves. The popular and trivial classes plane curves such as straight lines and quadrics are singular from the projective point of view. The next class is the class of $W$-curves, introduced by Klein and Lie, we collected some known properties of these curves (see, [3] and [4] for more details). The more important property of these curves, in light of Theorem 5, is that they are not regular. They are curves of constant projective curvature.

The first regular curves can be found in cubics and theorem 16 repeats the known result that projective classes of regular cubics can be described by one parameter. We give explicit formula to find this parameter.

The second important class of regular curves delivers by extremals of Study functional (cf. [7]). The corresponding Euler equation has order 10 and therefore projective classes of such extremals can be described by two parameters. Theorem 16 gives a constructive way to compute them.

2. Jets of curves

Let $\mathbb{P}^2$ be the real projective plane and let $J^k$ be the manifold of $k$ - jets of non-parametrized curves on the plane $\mathbb{P}^2$. If $L \subset \mathbb{P}^2$ is a plane curve we denote by $[L]_0^k \in J^k$ the $k$ -jet of the curve at the point $a \in L$.

We denote by $\pi_{k,l} : J^k \to J^l$, $k > l$, the natural projections:

$$\pi_{k,l} : [L]_0^k \mapsto [L]_0^l.$$ 

The structure of jet - manifolds can be described as follows: obviously $J^0 = \mathbb{P}^2$, and the fibres $\pi_{1,0}^{-1}(a)$, $a \in \mathbb{P}^2$, of the projection $\pi_{1,0}$ are projectivizations of the tangent planes $\mathbb{P}(T_a \mathbb{P}^2) = \mathbb{P}^1$, and fibres $\pi_{k,k-1}^{-1}([L]_0^{k-1})$, when $k \geq 2$, are affine lines.
The vector spaces associated with them are

\[ S^k \tau^*_a \otimes \nu_a, \]

where \( \tau^*_a = T^*_a L \) - cotangent space, and \( \nu_a = T_a \mathbb{P}^2 / T_a L \) - normal space to a curve.

Let \((x, u)\) be an affine chart on the plane and let \((x, u, u_1, \ldots, u_k)\) be the natural coordinates in the space of \(k\)-jets.

Here

\[ u_i \left( [L]^k_a \right) = \frac{\partial^i h}{\partial x^i} (b), \]

if \( L = L_h \overset{\text{def}}{=} \{ u = h(x) \} \) is a graph of function \( h \) in a neighborhood of point \( a = (b, h(b)) \).

In these coordinates the affine action is given by tensors

\[ \theta = \frac{\lambda}{k!} dx^k \otimes \overline{\partial}_a \in S^k \tau^*_a \otimes \nu_a, \]

and has the form

\[ (x, u, u_1, \ldots, u_{k-1}, u_k) \mapsto (x, u, u_1, \ldots, u_{k-1}, u_k + \lambda), \]

where \( \overline{\partial}_a = \partial_a \mod T_a L \).

Any smooth curve \( L \subset \mathbb{P}^2 \) determines curves \( L^{(k)} \subset J^k \), \( k \)-th prolongations of \( L \), formed by points \( [L]^k_a \) where point \( a \) runs over curve \( L \).

The action of projective group \( \text{SL}_3(\mathbb{R}) \) can be prolonged in manifolds \( J^k \) in the natural way:

\[ \phi^{(k)} : [L]^k_a \mapsto [\phi(L)]^k_a \]

where \( \phi \) is a projective transformation.

### 3. Model curves

The use of model curves is based on the following observation. Assume that we have a class \( \mathfrak{M} \) of plane curves which is projectively invariant and such that for any point \( x_k \in J^k \) there is a unique curve \( L = L(x_k) \in \mathfrak{M} \) such that \( x_k = [L]^k_a \), for \( a = \pi_k (x_k) \). Then points \( x_{k+1} = [L(x_k)]^{k+1}_a \) can be taken as basic points in the affine line \( \pi^{-1}_{k+1, k} (x_k) \) and the corresponding section \( m : J^k \to J^{k+1} \) we consider as the zero section in the line bundle \( \pi_{k+1, k} : J^{k+1} \to J^k \).

Let now \( L \subset \mathbb{P}^2 \) be an arbitrary curve. Then curves \( L^{(k+1)} \subset J^{k+1} \) and \( m(L^{(k)}) \subset J^{k+1} \) differs on element \( \Theta_L \in S^{k+1} T^*_L \otimes \nu_L \).

The last tensor is a projective differential invariant of order \((k + 1)\) in the sense that

\[ \phi^* (\Theta_{\phi(L)}) = \Theta_L, \]

for arbitrary projective transformation \( \phi \).

Below we’ll realize this scheme for different classes of projective curves.
3.1 Straight Lines

Let $\mathcal{M}$ be the class straight lines on the projective plane. Obviously, for any point $x_1 \in J^1$ there is a unique line $L(x_1)$, such that $x_1 = [L(x_1)]^1_a$.

Therefore, the above construction leads us projective differential invariant of order 2

$$\Theta_{2L} \in S^2 T^*_L \otimes \nu_L.$$  

If $L = L_h$ is the graph of function $u = h(x)$ in the affine coordinates, then the restriction of tensor $\Theta_2$ on this curve has the form:

$$\Theta_{2L} = h''(x) \frac{dx^2}{2!} \otimes \bar{\partial}_u.$$

We write

$$\Theta_2 = u_2 \frac{dx^2}{2!} \otimes \bar{\partial}_u$$

in the jet coordinates and

$$\Theta_{2L} = \Theta_2 |_{L^{(2)}}.$$  

Denote by $\Pi_2 \subset J^2$ the submanifold, where $\Theta_2 = 0$.

Then the points

$$\Pi_2 (L) = \Pi_2 \cap L^{(2)}$$

are precisely inflection or flex points on the curve, i.e. points where tangent lines have 2-rd order contact with the curve.

3.2 Quadrics

Let $\mathcal{M}$ be now the class of quadrics on the projective plane.

In affine coordinates each such quadrics is defined by the equation:

$$Q_2 = a_{11} u^2 + 2a_{12} xu + a_{22} x^2 + 2a_1 u + 2a_2 x + a_3 = 0.$$  

Taking derivatives of $Q_2$ up to order 5 and eliminating $a$’s coefficients we arrive at equation

$$(9u_5u_2^2 + 40u_3^3 - 45u_2u_4u_3)u_2 = 0.$$  

If we really will consider only quadrics ($u_2 \neq 0$), then we get the Monge equation:

$$9u_5u_2^2 + 40u_3^3 - 45u_2u_4u_3 = 0,$$

or

$$u_5 = \frac{5u_3u_4}{u_2} - \frac{40u_3^3}{9u_2^2}.$$  

In other words, for any point $x_4 \in J^4 \setminus \pi^{-1}_{4,1}(\Pi_2)$ there is a unique quadric $Q(x_4)$ such that $[Q(x_4)]^4_a = x_4$.  

244
Therefore, as above, for any curve $L$ we have projective differential invariant

$$\Theta_5 L \in S^2 T^*_L \otimes \nu_L,$$

where

$$\Theta_5 L = \left( h^{(5)} - 5 \frac{h^{(3)} h^{(4)}}{h^{(2)}} + \frac{40}{9} \frac{(h^{(3)})^3}{(h^{(2)})^2} \right) \frac{dx^5}{5!} \otimes \partial_u,$$

or

$$\Theta_5 = \left( u_5 - 5 \frac{u_3 u_4}{u_2} + \frac{40}{9} \frac{u_3^2}{u_2^2} \right) \frac{dx^5}{5!} \otimes \partial_u$$

in jet coordinates in the domain $J^5 \setminus \pi^{-1}_{5,2} (\Pi_2).$

Denote by $\Pi_5 \subset J^5 \setminus \pi^{-1}_{5,2} (\Pi_2)$ the submanifold, where $\Theta_5 = 0.$

Then the points

$$\Pi_5 (L) = \Pi_5 \cap L^{(5)}$$

we call Monge points.

They are the points where osculating quadrics have 5-th order contact with the curve.

### 3.3 Cubics

Let $\mathfrak{M}$ be now the class of cubics on the projective plane.

In affine coordinates each such quadrics is defined by the equation:

$$Q_3 = a_{111} u^3 + 3 a_{112} u^2 x + 3 a_{122} u x^2 + a_{222} x^3$$

$$+ a_{11} u^2 + 2 a_{12} x u + a_{22} x^2 + 2 a_1 u + 2 a_2 x + a_3 = 0.$$

Taking derivatives of $Q_3$ up to order 9 and eliminating $a$’s coefficients we arrive at equation (see, for example, [6]):

$$u_2 P_7 u_9 + P_8 = 0,$$

where $P_8$ is a polynomial of degree 10 and order 8,

$$P_7 = 7 (60)^{-3} \det (M_7)$$

is a a polynomial of degree 8 and order 7, and

$$M_7 = \begin{vmatrix}
120 u_3 & 30 u_4 & 6 u_5 & u_6 & u_7/7 \\
360 u_2 & 120 u_3 & 30 u_4 & 6 u_5 & u_6 \\
-180 u_2^2 & 0 & 20 u_3^2 & 10 u_3 u_4 & 2 u_3 u_5 + 5 u_4^2/4 \\
0 & 180 u_2^2 & 120 u_3 u_2 & 30 u_4 u_2 + 20 u_3^2 & 6 u_5 u_2 + 10 u_3 u_4 \\
0 & 0 & 180 u_2^2 & 180 u_3 u_2 & 60 u_3^2 + 45 u_4 u_2
\end{vmatrix}$$
more explicitly

\[
P_7 = -3360 u_2 u_3^6 u_4 - 810 u_2^5 u_3 u_4 u_7 + 1134 u_2^5 u_3 u_5 u_6 - 756 u_2^4 u_3^2 u_5^2 \\
+ 13230 u_2^4 u_3 u_4^2 u_5 - 2835 u_2^5 u_4 u_5^2 - 12600 u_2^3 u_3^3 u_4 u_5 - 189 u_2^6 u_6^2 \\
- 7875 u_2^3 u_3^2 u_4^3 + 720 u_2^4 u_3^3 u_7 - 4725 u_2^4 u_4^4 + 1200 u_3^8 \\
+ 1890 u_2^5 u_4^2 u_6 + 6720 u_2^2 u_3^5 u_5 + 31500 u_2^2 u_3^4 u_4^2 - 3150 u_2^4 u_3^2 u_4 u_6 \\
+ 162 u_2^6 u_5 u_7.
\]

Therefore,

\[
u_9 = -\frac{P_8}{u_2 P_7}
\]

for cubics.

In other words, for any point \(x_8 \in J^9 \setminus \left( \pi_{8,2}^{-1}(\Pi_2) \cup \pi_{8,7}^{-1}(\Pi_7) \right)\), where \(\Pi_7 = P_7^{-1}(0) \subset J^7\), there is a unique cubic \(Q(x_8)\) such that \([Q(x_8)]_9^8 = x_8\).

Therefore, as above, for any curve \(L\) we have projective differential invariant

\[
\Theta_{9L} \in S^{9}T^*_L \otimes \nu_L,
\]

where

\[
\Theta_9 = \left( u_9 + \frac{P_8}{u_2 P_7} \right) \frac{dx^9}{9!} \otimes \bar{\partial}_u
\]

in jet coordinates in the domain \(J^9 \setminus \left( \pi_{9,2}^{-1}(\Pi_2) \cup \pi_{9,7}^{-1}(\Pi_7) \right)\).

Denote by \(\Pi_9 \subset J^9 \setminus \left( \pi_{9,2}^{-1}(\Pi_2) \cup \pi_{9,7}^{-1}(\Pi_7) \right)\) the submanifold, where \(\Theta_9 = 0\).

Then the points

\[
\Pi_9(L) = \Pi_9 \cap L^{(9)}
\]

we call Monge cubic points.

They are the points where osculating cubics have 9-th order contact with the curve.

### 3.4 General Polynomial forms

Let \(\mathcal{M}\) be now the class of curves on the projective plane, having degree \(n\). Each such polynomial is defined by \(k(k + 3)/2\) coefficients. Hence, taking derivatives up to order \(j = k(k + 3)/2\) and eliminating these coefficients we arrive at equation of the form \(P_j u_j + P_{j-1}\)

### 4. \(\text{SL}_3(\mathbb{R})\)-orbits in the jet spaces

#### 4.1 \(J^2\)-orbits

The action of the projective group on the manifold of 1-jets is obviously transitive.
The stabilizer of point \((0, 0, 0) \in J^1\) is formed by matrices

$$A = \begin{bmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{22} & 0 \\ a_{31} & a_{32} & a_{33} \end{bmatrix}.$$ 

Action of such matrices on the fibre of projection \(\pi_{2,1} : J^2 \to J^1\) has the form:

$$A^{(2)} : (0, 0, 0, u_2) \mapsto (0, 0, 0, a_{11}^{-3} u_2).$$

Therefore, there is the only one open regular orbit \(\Pi_{20} = J^2 \setminus \Pi_2\) and the singular orbit \(\Pi_2\):

$$J^2 = \Pi_{20} \cup \Pi_2,$$

and points

\[p_{20} = (0, 0, 0, 1) \in \Pi_{20}, \quad p_2 = (0, 0, 0, 0) \in \Pi_2\]

can be taken as representatives.

### 4.2 \(J^3\)-orbits

Consider the action of the stabilizer of point \((0, 0, 0, 1)\) from the regular orbit \(\Pi_{20}\) on the fibre of projection \(\pi_{3,2} : J^3 \to J^2\).

This stabilizer is formed by matrices

$$A = \begin{bmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{22}^{2}a_{33}^{-1} & 0 \\ a_{31} & a_{32} & a_{33} \end{bmatrix},$$

and their action is the following affine action:

$$A^{(3)} : (0, 0, 0, 1, u_3) \mapsto (0, 0, 0, 1, \alpha_A u_3 + \beta_A),$$

where

$$\alpha_A = a_{33}a_{11}^{-1}, \quad \beta_A = 3 (a_{11}a_{31} - a_{12}a_{33}) a_{11}^{-2}.$$ 

Therefore, \(\Pi_{30} = \pi_{3,2}^{-1}(\Pi_{20})\) is the open regular orbit.

The stabilizer of the point \((0, 0, 0, 0)\) from the singular orbit \(\Pi_2\) formed by matrices

$$A = \begin{bmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{22} & 0 \\ a_{31} & a_{32} & a_{33} \end{bmatrix},$$

which act in the following way

$$A^{(3)} : (0, 0, 0, 0, u_3) \mapsto \left(0, 0, 0, \frac{a_{33}}{a_{11}^4} u_3\right).$$
Therefore, the preimage \( \pi_{3,2}^{-1}(\Pi_2) \) of the singular orbit is a union of two orbits
\( \Pi_{32} = \{(x, u, u_1, 0, 0)\} \) and \( \Pi_{31} = \pi_{3,2}^{-1}(\Pi_2) \setminus \Pi_{31} \) and \( J^3 \) has the following decomposition of \( SL_3(\mathbb{R}) \)-action:

\[
J^3 = \Pi_{30} \cup \Pi_{31} \cup \Pi_{32},
\]

where \( \Pi_{30} \) is the regular open orbit.

The following points
\( p_{30} = (0, 0, 0, 1, 0) \in \Pi_{30}, \ p_{31} = (0, 0, 0, 0, 1) \in \Pi_{31}, \ p_{32} = (0, 0, 0, 0, 0) \in \Pi_{32} \)
can be taken as representatives of the orbits.

**4.3 J^4-orbits**

Consider the action of the stabilizer of point \((0, 0, 0, 1, 0)\) from the regular orbit \( \Pi_{30} \) on the fibre of projection \( \pi_{4,3} : J^4 \to J^3 \).

This stabilizer is formed by matrices

\[
A = \begin{bmatrix}
    a_{11} & a_{11}a_{31}a_{33}^{-1} & 0 \\
    0 & a_{21}a_{33}^{-1} & 0 \\
    a_{31} & a_{32} & a_{33}
\end{bmatrix}
\]

with the following affine action:

\[
A^{(4)} : (0, 0, 0, 1, 0, u_4) \mapsto (0, 0, 0, 1, 0, a_{33}a_{31}^{-2}u_4 + (6a_{33}a_{32} - 3a_{31}^2)a_{11}^{-2}) .
\]

Therefore, \( \Pi_{40} = \pi_{4,3}^{-1}(\Pi_{30}) \) is an open regular orbit.

The stabilizer of point \((0, 0, 0, 0, 1)\) from the singular orbit \( \Pi_{31} \) is formed by matrices

\[
A = \begin{bmatrix}
    a_{11} & a_{12} & 0 \\
    0 & a_{21}a_{33}^{-1} & 0 \\
    a_{31} & a_{32} & a_{33}
\end{bmatrix}
\]

with the following affine action

\[
A^{(4)} : (0, 0, 0, 0, 1, u_4) \mapsto (0, 0, 0, 0, 1, a_{33}a_{11}^{-1}u_4 + 8a_{31}a_{11}^{-1}) .
\]

Therefore, \( \Pi_{41} = \pi_{4,3}^{-1}(\Pi_{31}) \) is an orbit.

Finally, the stabilizer of point \((0, 0, 0, 0, 0)\) from \( \Pi_{32} \) is formed by matrices

\[
A = \begin{bmatrix}
    a_{11} & a_{12} & 0 \\
    0 & a_{22} & 0 \\
    a_{31} & a_{32} & a_{33}
\end{bmatrix}
\]

with the following action

\[
A^{(4)} : (0, 0, 0, 0, 0, u_4) \mapsto (0, 0, 0, 0, 0, a_{33}^3a_{22}a_{11}^{-4}u_4) .
\]
Therefore, the preimage $\pi_{4,3}^{-1}(\Pi_{32})$ of the singular orbit $\Pi_{32}$ is a union of two orbits $\Pi_{43} = \{(x, u, u_1, 0, 0, 0)\}$ and $\Pi_{42} = \pi_{4,3}^{-1}(\Pi_{31}) \setminus \Pi_{43}$.

Summarizing, we see that there is the only one open and regular orbit $\Pi_{40}$ and three singular orbits $\Pi_{41}$, $\Pi_{42}$ and $\Pi_{43}$:

$$J^4 = \Pi_{40} \cup \Pi_{41} \cup \Pi_{42} \cup \Pi_{43}.$$ 

The following points

$$p_{40} = (0, 0, 0, 1, 0, 0) \in \Pi_{40}, \quad p_{41} = (0, 0, 0, 0, 1, 0) \in \Pi_{41},$$

$$p_{42} = (0, 0, 0, 0, 0, 1) \in \Pi_{42}, p_{43} = (0, 0, 0, 0, 0, 0) \in \Pi_{43}$$

can be taken as representatives of the orbits.

### 4.4 $J^5$-orbits

Let’s begin with preimage of regular orbit $\Pi_{40}$.

The stabilizer of point $(0, 0, 0, 1, 0, 0)$ is formed by matrices

$$A = \begin{pmatrix} a_{11} & a_{11}a_{31}a_{33}^{-1} & 0 \\ 0 & a_{13}^2a_{33}^{-1} & 0 \\ a_{31} & \frac{a_{31}a_{33}}{2} & a_{33} \end{pmatrix}$$

and has the following action on the fibre:

$$A^{(5)} : (0, 0, 0, 1, 0, 0, u_5) \longmapsto (0, 0, 0, 1, 0, 0, a_{33}^3a_{11}^{-3}u_5).$$

Therefore, the preimage $\pi_{5,4}^{-1}(\Pi_{40})$ of the regular orbit is a union two orbits: the singular one $\Pi_5$ and the open regular orbit $\Pi_{50} = \pi_{5,2}^{-1}(\Pi_{20}) \setminus \Pi_5$.

The stabilizer of point $(0, 0, 0, 0, 1, 0)$ from the singular orbit $\Pi_{41}$ is formed by matrices

$$A = \begin{pmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{13}^2a_{33}^{-2} & 0 \\ 0 & a_{32} & a_{33} \end{pmatrix}$$

and acts in the following way

$$A^{(5)} : (0, 0, 0, 0, 1, 0, u_5) \longmapsto (0, 0, 0, 0, 1, 0, a_{33}^3a_{11}^{-2}u_5 - 10a_{12}a_{33}^2a_{11}^{-3}).$$

Therefore, $\Pi_{51} = \pi_{5,4}^{-1}(\Pi_{41})$ is an orbit.

The stabilizer of point $(0, 0, 0, 0, 0, 1)$ from the singular orbit $\Pi_{42}$ is formed by matrices

$$A = \begin{pmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{13}^3a_{33}^{-3} & 0 \\ a_{31} & a_{32} & a_{33} \end{pmatrix}$$

249
and acts in the following way

\[ A^{(5)} : (0, 0, 0, 0, 1, u_5) \mapsto (0, 0, 0, 0, 1, a_{33}a_{11}^{-1} u_5 + 15a_{31}a_{11}^{-1}) . \]

Therefore, \( \Pi_{52} = \pi_{5,4}^{-1}(\Pi_{42}) \) is an orbit too.

Finally, the stabilizer of point \( (0, 0, 0, 0, 0) \) from the singular orbit \( \Pi_{43} \) is formed by matrices

\[
A = \begin{bmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{22} & 0 \\ a_{31} & a_{32} & a_{33} \end{bmatrix}
\]

and acts as following

\[ A^{(5)} : (0, 0, 0, 0, 0, u_5) \mapsto (0, 0, 0, 0, 1, a_{33}a_{11}^{-1} + 15a_{31}a_{11}^{-1} u_5). \]

Therefore, the preimage \( \pi_{5,4}^{-1}(\Pi_{43}) \) is a union of two orbits:

\[ \Pi_{54} = \{(x, u, u_1, 0, 0, 0)\} \]

and

\[ \Pi_{53} = \pi_{5,4}^{-1}(\Pi_{43}) \setminus \Pi_{54}. \]

Summarizing, we conclude that \( \text{SL}_3(\mathbb{R}) \)-action in \( J^5 \) has the following orbit decomposition:

\[ J^5 = \Pi_{50} \cup \Pi_5 \cup \Pi_{51} \cup \Pi_{52} \cup \Pi_{53} \cup \Pi_{54}, \]

where \( \Pi_{50} \) is the only regular open orbit.

The following points

\[
p_{50} = (0, 0, 0, 1, 0, 0, 1) \in \Pi_{50}, \quad p_5 = (0, 0, 0, 1, 0, 0, 0) \in \Pi_5, \\
p_{51} = (0, 0, 0, 0, 1, 0, 0) \in \Pi_{51}, \quad p_{52} = (0, 0, 0, 0, 0, 1, 0) \in \Pi_{52}, \\
p_{53} = (0, 0, 0, 0, 0, 0, 1) \in \Pi_{53}, \quad p_{54} = (0, 0, 0, 0, 0, 0, 0) \in \Pi_{54}
\]

can be taken as representatives of the orbits.

### 4.5 \( J^6 \)-orbits

Let’s begin with preimage of regular orbit \( \Pi_{50} \). The stabilizer of point \( p_{50} \) is formed by matrices

\[
A = \begin{bmatrix} a_{33} & a_{31} & 0 \\ 0 & a_{33} & 0 \\ a_{31} & \frac{1}{2}a_{31}a_{33}^{-1} & a_{33} \end{bmatrix}
\]

which act in the following way

\[ A^{(6)} : (0, 0, 0, 1, 0, 0, 1, u_6) \mapsto (0, 0, 0, 1, 0, 0, 1, u_6 + \frac{3a_{31}}{a_{33}}), \]
and therefore $\Pi_{60} = \pi_{6,5} (\Pi_{50})$ is an open regular orbit.

The stabilizer of the point $p_5$ is formed by matrices

$$A = \begin{bmatrix} a_{11} & a_{11}a_{31}a_{33}^{-1} & 0 \\ 0 & a_{11}^2a_{33}^{-1} & 0 \\ a_{31} & \frac{1}{2}a_{31}^3a_{33}^{-1} & a_{33} \end{bmatrix}$$

with the following action:

$$A^{(6)} : (0, 0, 0, 1, 0, 0, u_6) \mapsto (0, 0, 0, 1, 0, 0, a_{33}^4a_{11}^{-4}u_6).$$

Therefore, preimage $\pi_{6,5} (\Pi_5)$ is a union of three orbits

$$\pi_{6,5} (\Pi_5) = \Pi_{61}^+ \cup \Pi_{61}^- \cup \Pi_{62}$$

with the following representatives

$$p_{61}^+ = (0, 0, 0, 1, 0, 0, 0), \quad p_{61}^- = (0, 0, 0, 1, 0, 0, 0, 1), \quad p_{62} = (0, 0, 0, 1, 0, 0, 0, 0).$$

The stabilizer of the point $p_{51} = (0, 0, 0, 0, 1, 0, 0) \in \Pi_{51}$ contains matrices

$$A = \begin{bmatrix} a_{11} & 0 & 0 \\ 0 & a_{11}a_{33}^{-2} & 0 \\ 0 & a_{32} & a_{33} \end{bmatrix}$$

and acts in the following way

$$A^{(6)} : (0, 0, 0, 0, 1, 0, 0, u_6) \mapsto (0, 0, 0, 1, 0, 0, a_{33}^3a_{11}^{-3}u_6 + 40a_{11}^{-3}a_{32}a_{33}^2).$$

Therefore, $\Pi_{63} = \pi_{6,5}^{-1} (\Pi_{51})$ is an orbit.

The stabilizer of the point $p_{52} = (0, 0, 0, 0, 0, 1, 0) \in \Pi_{52}$ formed by matrices

$$A = \begin{bmatrix} a_{11} & a_{12} & 0 \\ 0 & a_{11}a_{33}^{-3} & 0 \\ 0 & a_{32} & a_{33} \end{bmatrix}$$

and acts in the following way

$$A^{(6)} : (0, 0, 0, 0, 0, 1, 0, u_6) \mapsto (0, 0, 0, 1, 0, 0, 0, a_{33}^2a_{11}^{-2}u_6).$$

Therefore, $\pi_{6,5}^{-1} (\Pi_{52})$ is a union of three orbits

$$\pi_{6,5}^{-1} (\Pi_{52}) = \Pi_{64}^+ \cup \Pi_{64}^- \cup \Pi_{65}$$
with representatives
\[ p_{64}^+ = (0, 0, 0, 0, 0, 1, 0, 1), \quad p_{64}^- = (0, 0, 0, 0, 0, 1, 0, -1), \]
\[ p_{65} = (0, 0, 0, 0, 0, 1, 0, 0). \]
The stabilizer of the point \( p_{54} = (0, 0, 0, 0, 0, 1) \in \Pi_{53} \) formed by matrices
\[ A = \begin{vmatrix}
    a_{11} & a_{12} & 0 \\
    0 & a_{11}^{-4} & 0 \\
    a_{13} & a_{32} & a_{33}
\end{vmatrix} \]
with the following action
\[ A^{(6)} : (0, 0, 0, 0, 0, 0, 1, u_6) \longmapsto \left( 0, 0, 0, 0, 0, 0, 1, a_{33}a_{11}^{-1}u_6 + 24a_{31}a_{11}^{-1} \right). \]
Therefore, \( \Pi_{66} = \pi_{6,5}^{-1}(\Pi_{53}) \) is an orbit with representative
\[ p_{66} = (0, 0, 0, 0, 0, 0, 1, 0). \]
Finally, the stabilizer of the point \( p_{54} = (0, 0, 0, 0, 0, 1) \in \Pi_{54} \) is formed by matrices
\[ A = \begin{vmatrix}
    a_{11} & a_{12} & 0 \\
    0 & a_{22} & 0 \\
    a_{13} & a_{32} & a_{33}
\end{vmatrix} \]
which act in the following way:
\[ A^{(6)} : (0, 0, 0, 0, 0, 0, 0, u_6) \longmapsto \left( 0, 0, 0, 1, 0, 0, 0, a_{33}a_{11}^{-1}u_6 \right). \]
Therefore, the preimage \( \pi_{6,5}^{-1}(\Pi_{54}) \) is a union of two orbits \( \Pi_{67} \) and \( \Pi_{68} \) with representatives
\[ p_{67} = (0, 0, 0, 0, 0, 0, 1) \quad \text{and} \quad p_{68} = (0, 0, 0, 0, 0, 0, 0) \]
respectively.
Summarizing, we get the following result.

**Theorem 4.1.** \( \text{SL}_3(\mathbb{R}) \)-action in \( J^6 \) splits into the following orbit decomposition:
\[ J^6 = \Pi_{60} \cup \Pi_{61}^+ \cup \Pi_{61}^- \cup \Pi_{62} \cup \Pi_{63} \cup \Pi_{64}^+ \cup \Pi_{64}^- \cup \Pi_{65} \cup \Pi_{66} \cup \Pi_{67} \cup \Pi_{68}, \]
with the following representatives
\[ p_{60} = (0, 0, 0, 1, 0, 0, 1, 0), \quad p_{61}^+ = (0, 0, 0, 1, 0, 0, 1, 0), \]
\[ p_{61}^- = (0, 0, 0, 1, 0, 0, 0, -1), \quad p_{62} = (0, 0, 0, 1, 0, 0, 0, 0), \]
\[ p_{63} = (0, 0, 0, 1, 0, 0, 0, 0), \quad p_{64}^+ = (0, 0, 0, 0, 0, 1, 0, 1), \]
\[ p_{64}^- = (0, 0, 0, 0, 0, 1, 0, -1), \quad p_{65} = (0, 0, 0, 0, 0, 1, 0, 0), \]
\[ p_{66} = (0, 0, 0, 0, 0, 1, 0), \quad p_{67} = (0, 0, 0, 0, 0, 0, 1), \]
\[ p_{68} = (0, 0, 0, 0, 0, 0, 0). \]
As a corollary of this theorem we get the following SL_3(\mathbb{R})-classification of 6-jets of projective curves.

**Theorem 4.2.** Let \( L \subset \mathbb{P}^2 \) be a smooth projective curve. Then for any point \( a \in L \) there are projective coordinates \((x, y)\) such that \( x(a) = y(a) = 0 \) and the curve can be written in the form \( y = p(x) + \varepsilon(x) \), where function \( \varepsilon(x) \) has seventh order of smallness and polynomial \( p(x) \) has one of the following form:

\[
\begin{align*}
p_{60}(x) &= x^2 + x^5, \\
p_{61}(x) &= x^2 \pm x^6, \\
p_{62}(x) &= x^2, \\
p_{63}(x) &= x^3, \\
p_{64}(x) &= x^4, \\
p_{65}(x) &= x^5, \\
p_{66}(x) &= x^6, \\
p_{67}(x) &= x^6, \\
p_{68}(x) &= 0,
\end{align*}
\]

where polynomials \( p_{ij} \) correspond to orbits \( \Pi_{ij} \).

### 4.6 Stabilizers of regular orbit

The open orbit \( \Pi_{60} = J^6 \setminus \pi_{6,2}(\Pi_2) \setminus \pi_{6,5}(\Pi_5) \) we call regular, and elements of this orbit we also call regular. A point \( a \in L \) on a smooth projective curve we call regular if \( [L]^6_a \notin \Pi_{60} \), if not the point is calling singular. It was to note that our definitions differ from the standard ones: both regular and singular points belong to smooth curve, and their singularity has projective nature. Remark also that the previous theorem states that the regular orbit is connected even though singular orbits \( \Pi_2 \) and \( \Pi_5 \) have codimension 1.

Before to consider differential invariants of projective curves we’ll finish this section by description of stabilizers of regular point in \( J^k \), when \( k = 2, 3, 4, 5, 6 \).

Take 2-jet \( p_{20} = (0, 0, 0, 1) \). Then the stabilizer is a 4-dimensional group and consist of matrices

\[
\text{St}_2 = \begin{bmatrix}
1 & \alpha & 0 \\
0 & \beta^{-1} & 0 \\
\gamma & \delta & \beta
\end{bmatrix},
\]

where \((\alpha, \gamma, \delta) \in \mathbb{R}^3, \beta \in \mathbb{R} \setminus 0\).

For 3-jet \( p_{30} = (0, 0, 0, 1, 0) \) the stabilizer is a 3-dimensional group and consist of matrices

\[
\text{St}_3 = \begin{bmatrix}
1 & \alpha & 0 \\
\alpha \beta & \gamma & \beta
\end{bmatrix},
\]

where \((\alpha, \gamma) \in \mathbb{R}^2, \beta \in \mathbb{R} \setminus 0\).

For 4-jet \( p_{40} = (0, 0, 0, 1, 0, 0) \) the stabilizer is a 2-dimensional group and consist of matrices

\[
\text{St}_4 = \begin{bmatrix}
1 & \alpha & 0 \\
\alpha \beta & \gamma & \beta
\end{bmatrix},
\]

253
where $\alpha \in \mathbb{R}, \beta \in \mathbb{R} \setminus 0$.

For 5-jet $p_{50} = (0, 0, 0, 1, 0, 0, 1)$ the stabilizer is a 1-dimensional group and consist of matrices

$$
\text{St}_5 = \left\{ \begin{bmatrix} 1 & \alpha & 0 \\ 0 & 1 & 0 \\ \alpha & \frac{1}{2} \alpha^2 & 1 \end{bmatrix} \right\},
$$

and for 6-jet $p_{60} = (0, 0, 0, 1, 0, 0, 1, 0)$ the stabilizer is trivial.

5. Projective Invariants

5.1 Relative Invariants

As we have seen, functions

$$
P_2 = u_2,
$$

$$
P_5 = u_5 - \frac{5 u_3 u_4}{u_2} + 40 \frac{u_3^3}{9 u_2^2}
$$

determine singular orbits $\Pi_2$ and $\Pi_5$.

Therefore, they are relative invariants of the $\text{SL}_3(\mathbb{R})$- action.

Indeed, it is easy to check that

$$
X^{(2)} (P_2) = \alpha_2 (X) \cdot P_2,
$$

where

$$
X = \left( 2 a_{1,1} x + a_{2,2} x + a_{1,2} u + a_{1,3} - a_{3,1} x^2 - a_{3,2} x u \right) \partial_x \\
+ \left( a_{1,1} u + 2 a_{2,2} u + a_{2,1} x + a_{2,3} - a_{3,1} x u - a_{3,2} u^2 \right) \partial_u
$$

is a general element of Lie algebra $\mathfrak{sl}_3(\mathbb{R})$, and

$$
\alpha_2 (X) = -3 \left( a_{1,2} - a_{3,2} x \right) u_1 - 3 a_{1,1} + 3 a_{3,1} x
$$

the corresponding 1-cocycle.

Also

$$
X^{(5)} (P_5) = \alpha_5 (X) \cdot P_5,
$$

where

$$
\alpha_5 (X) = -6 \left( a_{1,2} - a_{3,2} x \right) u_1 + 3 a_{3,2} u - 9 a_{1,1} + 9 a_{3,1} x - 3 a_{2,2}.
$$

It is also easy to see that the function $P_7$ is a relative invariant.

Indeed,

$$
X^{(7)} (P_7) = \alpha_7 (X) \cdot P_7,
$$

254
where
\[
\alpha_7(X) = -32(a_{1,2} - a_{3,2}x)u_1 - 40a_{1,1} + 40a_{3,1}x - 8a_{2,2} + 8a_{3,2}u.
\]
Cocycles \(\alpha_2, \alpha_5\) and \(\alpha_7\) are not independent, and we have
\[
16\alpha_2 + 8\alpha_5 - 3\alpha_7 = 0.
\]
Another relative invariant we can get from the volume form \(\Omega = dx \wedge du\) because
\[
X(\Omega) = \alpha_0(X) \Omega,
\]
where
\[
\alpha_0(X) = 3a_{1,1} + 3a_{2,2} - 3a_{3,1}x - 3a_{3,2}u,
\]
and
\[
\alpha_0 - 2\alpha_2 + \alpha_5 = 0.
\]
The last relative invariant we get from the contact form \(\omega = du - u_1dx\).
In this case
\[
X^{(1)}(\omega) = \alpha_1(X)\omega,
\]
where 1-cocycle \(\alpha_1\) has the following form
\[
\alpha_1(X) = -(a_{1,2} - a_{3,2}x)u_1 + a_{1,1} + 2a_{2,2} - a_{3,1}x - 2a_{3,2}u,
\]
and
\[
2\alpha_0 - 3\alpha_1 + \alpha_2 = 0.
\]
These relations between 1-cocycles allow us to construct the following invariant tensors.

**Theorem 5.1.** The following tensors on jet spaces are \(\text{SL}_3(\mathbb{R})\)-invariants:

**Function**
\[
Q_7 = \frac{P_7}{P_5^{8/3}P_2^{16/3}} \in C^\infty \left(\pi_{7,6}^{-1}(\Pi_{60})\right).
\]

**Differential 1-form**
\[
\omega_5 = \frac{P_5^{2/3}}{P_2^{5/3}}\omega \in \Omega^1(\Pi_{50}).
\]

**Differential 2-form**
\[
\Omega_5 = \frac{P_5}{P_2^{2}}\Omega \in \Omega^2(\Pi_{50}).
\]
5.2 Algebra of projective differential invariants

Let's denote by $\tau_k$ and $\nu_k$ the vector bundles on $J^k$ induced by projection $\pi_{k,1}$ from the canonical bundles $\tau_1, \nu_1$ on $J^1$, where

$$\begin{align*}
\tau_1 ([L]^1_a) &= T_a L, \\
\nu_1 ([L]^1_a) &= T_a \mathbb{P}^2 / T_a L.
\end{align*}$$

As we have seen symmetric differential forms

$$\Theta_2 = u_2 \frac{dx^2}{2!} \otimes \overline{d} u \in S^2 (\tau^*_2) \otimes \nu_2$$

and

$$\Theta_5 = \left( u_5 - \frac{5 u_3 u_4}{u_2} + \frac{40 u_3^3}{9 u_2^2} \right) \frac{dx^5}{5!} \otimes \overline{d} u \in S^5 (\tau^*_5) \otimes \nu_5$$

are $\text{SL}_3(\mathbb{R})$-invariants.

Remark that all bundles $\tau_k$ and $\nu_k$ are 1-dimensional. Therefore, there exists a symmetric 3-form $\sigma \in S^3 (\tau^*_5)$ such that

$$\Theta_5 = 60 \sigma \cdot \Theta_2.$$  

We call $\sigma$ as a Study 3-form.

This form is obviously $\text{SL}_3(\mathbb{R})$-invariant and in affine coordinates can be written as follows

$$\sigma = \frac{P_5}{P_2} dx^3.$$  

In addition to Study form we introduce a Study derivation as such total derivation $\nabla$ that

$$\sigma (\nabla, \nabla, \nabla) = 1.$$  

Once more, in affine coordinates this derivation has the form

$$\nabla = \frac{P_2^{1/3}}{P_5^{1/3}} \frac{d}{dx}.$$  

This is $\text{SL}_3(\mathbb{R})$-invariant derivation.

It is easy to check that invariant $Q_7$ is an affine function in $u_7$ having the form

$$Q_7 = \frac{P_2^{2/3}}{P_5^{5/3}} u_7 + \cdots.$$  

Applying the Study derivation we get an 8-th differential invariant

$$Q_8 = \nabla (Q_7) = \frac{P_2}{P_5^2} u_8 + \cdots, \quad (5.1)$$
and

$$Q_9 = \nabla (Q_8) = \frac{P_2}{P_5^7} u_9 + \cdots.$$  

Continue in this way we get differential invariants in each order $k \geq 7$:

$$Q_k = \nabla^{k-7} (Q_7) = \frac{P_2^{k-5}}{P_5^{k-3}} u_k + \cdots$$

These relations show that differential invariants $Q_7, \ldots, Q_k$, separate $\text{SL}_3(\mathbb{R})$-orbits in $J^k$ if their projection to $J^6$ coincides with regular orbit $\Pi_{60}$. We call such orbits regular.

Let us specify now the notion of differential invariant for this $\text{SL}_3(\mathbb{R})$-action.

First of all remark that all bundles $\pi_{k,k-1} : J^k \to J^{k-1}$ are affine, when $k \geq 2$. Therefore, we can talk about functions which are polynomial, or algebraic in derivatives $u_k, k \geq 2$.

We say that a function $f$ defined in open and dense domain in manifold $k$-jets $J^k$ is a $\text{SL}_3(\mathbb{R})$-differential invariant (or simply projective differential invariant) of order $k$ if

- $X^{(k)} (f) = 0$, for any vector field $X \in \mathfrak{sl}_3(\mathbb{R})$, and
- function $f$ is a polynomial with respect to $u_\sigma, \sigma \geq 2$, and $P_2^{\pm 1/3}, P_5^{\pm 1/3}$.

**Theorem 5.2.**

1. Any projective differential invariant of order $k$ is a polynomial of invariants $Q_7, \ldots, Q_k$.

2. The algebra differential invariants separates regular orbits.

**Proof.** We’ll use induction in $k$. Let $Q$ be a differential invariant of order $k$ which is a polynomial of degree $n$ in $u_k$. Then, due to fact that $Q_k$ is a polynomial of degree 1 in $u_k$, we can represent $Q$ in the following way

$$Q = a_n Q^n_k + \cdots a_1 Q + a_0,$$

where $a_i$ are functions on $(k-1)$-jets.

Applying vector fields $X \in \mathfrak{sl}_3(\mathbb{R})$ to both sides of this relation, we get

$$X^{(k-1)} (a_n) Q^n_k + \cdots + X^{(k-1)} (a_1) Q_k + X^{(k-1)} (a_0) = 0.$$  

Therefore, $X^{(k-1)} (a_i) = 0$ for all $i = 0, \ldots, n, X \in \mathfrak{sl}_3(\mathbb{R})$, and we can use induction. □
6. Projective equivalence of plane curves

6.1 $\text{SL}_3(\mathbb{R})$- action

Let $L$ and $\tilde{L}$ be smooth plane curves, and let $L^{(k)}, \tilde{L}^{(k)} \subset J^k$ be their prolongations. We say that $L$ and $\tilde{L}$ are projectively equivalent if $g(L) = \tilde{L}$, for some element $g \in \text{SL}_3(\mathbb{R})$.

Let's $Q_k(L) = Q_k|_{L^{(k)}}$ be the value of invariant $Q_k$ on the curve $L$.

Function $Q_7(L)$ is called projective curvature of the curve.

We will consider such curves $L$ that function $Q_7(L)$ is a local coordinate on it. It is equivalent that function $\nabla (Q_7) = Q_8$ does not vanish on $L$.

To distinguish this situation we say that curve $L$ is a regular at point $a \in L$, if its 5-jet belongs to the regular orbit, $[L]_5^a \in \Pi_{50}$, and $Q_8(L)$ does not vanish at point $a \in L$.

Therefore, in a neighborhood of a regular point function $Q_7(L)$ is a local coordinate and

$$Q_8(L) = \Phi (Q_7(L))$$

for some smooth function $\Phi$.

We call this function defining function of the curve.

We say that two plane curves $L$ and $\tilde{L}$ are projectively equivalent at points $a \in L$ and $\tilde{a} \in \tilde{L}$ if there exist a projective transformation $\phi$ such that $\phi(a) = \tilde{a}$ and image $\phi(L)$ of curve $L$ and $\tilde{L}$ coincide in a neighborhood of point $\tilde{a}$.

**Theorem 6.1.** Two plane curves $L$ and $\tilde{L}$ are projectively equivalent in neighborhoods of regular points $a \in L$ and $\tilde{a} \in \tilde{L}$ if and only if $Q_7(L)(a) = Q_7(\tilde{L})(\tilde{a})$ and their defining functions coincide in a neighborhood of point $Q_7(L)(a)$.

**Proof.** The necessity condition is obvious. Let's prove the sufficiency, and let $\Phi$ be the defining function. Consider ordinary differential equation

$$Q_8 - \Phi (Q_7) = 0$$

(6.1)

of the 8-th order.

Curves $L$ and $\tilde{L}$ are local solutions of this equation.

Relation (5.1) shows that solutions of the above differential equation are uniquely defined by their 8-jets.

Values of $Q_7$ and $Q_8$ on 8-jets $[L]_8^a$ and $[\tilde{L}]_8^\tilde{a}$ equal and therefore these jets belong to the regular orbit. Therefore,

$$\phi^{(8)}([L]_8^a) = [\tilde{L}]_8^\tilde{a},$$

258
for some projective transformation \( \phi \).

Moreover, projective transformations are symmetries of differential equation (6.1). Hence, \( \phi (L) \) is a solution (6.1) too. But \( \text{8-jets of } \tilde{L} \text{ and } \phi (L) \) at point \( \tilde{a} \) equal. Therefore, due to uniqueness of solutions, \( \tilde{L} = \phi (L) \). □

Theorem 2 allows us to get normal forms of plane curves in a neighborhood of regular point.

Theorem 6.2. Let \( L \) be a plane curve and let \( a \in L \) be a regular point. Then there are affine coordinates \((x, y)\) in a neighborhood \( a \in L \), such that \( x(a) = y(a) = 0 \), and curve \( L \) is given by equation \( y = Y(x) \), where

\[
Y(x) = x^2 + \frac{2}{5}x^5 + \frac{108}{35}k_7x^7 + \left( \frac{1}{2} + \frac{81}{35}k_8 \right)x^8 + \left( \frac{1944}{35}k_7^2 + \frac{54}{35}k_9 \right)x^9 + \\
+ \left( \frac{54}{5}k_7^2 + \frac{2916}{25}k_7k_8 + \frac{162}{175}k_9 \right)x^{10} + \cdots,
\]

and \( k_i \) are values of \( Q_i(L) \) at point \( a \).

Remark 6.3. If \( \Phi \) is the defining function of the curve then coefficients \( k_i \) can be computed as follows:

\[
k_8 = \Phi(k_7), \quad k_9 = \Phi'(k_7)\Phi(k_7), \quad k_{10} = \Phi''(k_7)\Phi^2(k_7) + \Phi'(k_7)^2\Phi(k_7).
\]

6.2 Cubics

As an example of application of the above theorem let’s consider cubic curves. As we have seen these curves are solutions of equation

\[
u_2P_7u_9 + P_8 = 0.
\]

The left hand side of the equation is an obviously relative invariant.

This invariant can be written in terms of the known invariants as follows:

\[
(P_2P_5)^5 \left( -12600 Q_7 Q_9 + 14175 Q_8^2 + 1225 Q_8 - 259200 Q_7^3 + 343 \right).
\]

Therefore, if the cubic curve is an irreducible, i.e. not union of quadric and straight lines, then this curve satisfies the 9-th order differential equation

\[
-12600 Q_7 Q_9 + 14175 Q_8^2 + 1225 Q_8 - 259200 Q_7^3 + 343 = 0. \quad (6.2)
\]

The leading term of the last equation has the form

\[
-12600 \frac{Q_7 P_2^3}{P_5^5} u_9 + \cdots.
\]

259
Singularities for this equation in regular orbit belong to hyper surface \( Q_7 = 0 \).

In other words, on cubic curves we have three types of singularities:

- **general singular points**: 5-jet of the curve belongs to a singular orbit,
- **non regular points**: invariant \( Q_8 \) vanishes,
- **projectively flat points**: projective curvature \( Q_7 \) vanishes.

**Theorem 6.4.** Two plane connected cubic curves are projectively equivalent if and only if there are regular points on them where projective curvatures and their Study derivatives coincide.

**Proof.** The proof of local projective equivalency is similar to proof of theorem 5. The rest follows from the fact that cubics are algebraic curves. □

**Remark 6.5.** This result can be reformulated as follows. Let \( L \) be a plane curve. Define a new plane curve \( \mathcal{I}(L) \) as a image of the map \( a \in L \mapsto (Q_7(L)(a), Q_8(L)(a)) \in \mathcal{I}(L) \), and let \( \mathcal{I}_0(L) \subset \mathcal{I}(L) \) is the image of regular points. Then the above theorem claims, that two connected cubics \( L \) and \( \tilde{L} \) are projectively invariant if and only if \( \mathcal{I}_0(L) = \mathcal{I}_0(\tilde{L}) \).

7. Special curves on projective plane

7.1 W-curves

Two classes of projective curve we get from description of singular orbits: straight lines and quadrics. The third class come from the description of singularities for cubics: these are curves of zero projective curvature, or solutions of differential equation of 7-th order:

\[ Q_7 = 0. \]

This class is a subclass of so-called W-curves, introduced by Lie and Klein in ([4]).

Namely, straightforward computations show the following lemma is valid.

**Lemma 7.1.** \( \text{SL}_3(\mathbb{R}) \)-orbits are transversal to curve \( L^{(8)} \) at points where \( Q_8 \neq 0 \).
Therefore, curves $L$ for which $\text{SL}_3(\mathbb{R})$-orbits of prolongations $L^{(8)}$ have dimension less than 9 should be solutions of the differential equation $Q_8 = 0$.

In other words, such curves have constant projective curvature. They are called $W$-curves (see, [3]).

It follows from the above lemma that trajectories of vector fields from our Lie algebra $\mathfrak{sl}_3$ are $W$-curves. Counting dimensions shows that the dimension of the space of solutions passing through a point $a \in \mathbb{P}^2$ for the differential equation $Q_8 = 0$ at regular point $a \in \mathbb{P}^2$ equals 7 that coincide with dimension of nonparametric trajectories of vector fields from $\mathfrak{sl}_3$.

The 3-rd description of $W$-curves was proposed by Klein and Lie. Namely, let’s take three straight lines $l_1, l_2$ and $l_3$ on projective plane which are in general position and a plane curve $L$. Considering tangent line $T_a L$ as a straight line on the plane, we define a number $j_L (a)$ to be equal the value of $j$-invariant for 4 points $[a, T_a L \cap l_1, T_a L \cap l_2, T_a L \cap l_3]$ on $T_a L$. Consider now such curves for which $j$-number $j_L$ is a constant. They are also $W$-curves.

We have the following equivalent description of regular $W$-curves (see also [3]).

**Theorem 7.2.**
1. $W$-curves are solutions of 8-th order differential equation $Q_8 = 0$.
2. $W$-curves are non parametrized trajectories of vector fields from the projective Lie algebra $\mathfrak{sl}_3$.
3. $W$-curves are curves of constant projective curvature.
4. If projective curvature $Q_7(L)$ of a curve $L$ is a constant and equal $k \neq 0$, then the $j$-number of this curve equal $\frac{k^3}{k^3 - \lambda}$, where $\lambda = \frac{675}{21.952}$.

**Corollary 7.3.** If a regular cubic is a $W$-curve then its projective curvature equals

$$\frac{7\sqrt{5}}{360},$$

and $j$-number equals

$$\frac{7^6}{98297351}.$$

### 7.2 Study extremals

Another class of curves we obtain from the Study differential.

To this end let’s consider the following functional

$$L \mapsto \int_L \sqrt{\sigma},$$
or in affine coordinates
\[ y(x) \mapsto \int_a^b \frac{\sqrt[9]{y^{(5)}(y^{(2)})^2 + 40(y^{(3)})^3 - 45y^{(2)}y^{(3)}y^{(4)}}}{y^{(2)}} \, dx, \]
assuming that \( L \) is not a straight line, and call it Study functional.

Straightforward computations show that the following theorem is valid.

**Theorem 7.4.** Extremals of the Study functional are solutions of the following differential equation of the 10-th order:

\[
\frac{P_5}{P_2^2} (Q_{10} - 24Q_7Q_8) = 0. \tag{7.1}
\]

**Corollary 7.5.** \( W \)-curves are extremals of the Study functional.

**Corollary 7.6.** If a regular cubic \( L \) is an extremal of the Study functional then \( L \) is the \( W \)-curve.

# 8. Defining functions

In this section we consider a behavior of defining functions for cubics and Study extremals. It is worth to note that for straight lines, quadrics and \( W \)-curves the defining functions do not exist.

## 8.1 Cubics

Let \( \Phi \) be the defining function of a cubic \( L \) considered in a neighborhood of regular point. Then, applying the Study derivative to the relation \( Q_8 = \Phi(Q_7) \), we get \( Q_9 = \Phi'(Q_7)\Phi(Q_7) \). Relation (6.2) can be rewritten now as a differential equation for defining function \( \Phi(\tau) \):

\[
\frac{343}{36} - 259200 \tau^3 - 12600 \tau \Phi \Phi' + 14175 \Phi^2 + 1225 \Phi = 0.
\]

Integrating this equation we get the following relation between invariants \( Q_7 \) and \( Q_8 \) which depends on arbitrary constant \( c \) and has the following form

\[
F^3 + cGQ_7^9 = 0,
\]

where

\[
F = \frac{49}{147456} Q_8^4 + \frac{343}{3317760} Q_8^3 + \left( \frac{2401}{199065600} + \frac{7}{192} Q_7^3 \right) Q_8^2
\]

\[
+ \left( -\frac{49}{25920} Q_7^3 + \frac{16807}{2687385600} \right) Q_8
\]

\[
+ \left( Q_7^3 - \frac{343}{1036800} \right) \left( Q_7^3 - \frac{343}{9331200} \right)
\]

\[
= \frac{211}{199065600} Q_8^3 + \left( \frac{2401}{199065600} + \frac{7}{192} Q_7^3 \right) Q_8^2
\]

\[
+ \left( -\frac{49}{25920} Q_7^3 + \frac{16807}{2687385600} \right) Q_8
\]

\[
+ \left( Q_7^3 - \frac{343}{1036800} \right) \left( Q_7^3 - \frac{343}{9331200} \right)
\]

\[
(8.1)
\]
and
\[ G = 117649 - 6401203200 Q_7^3 + 18151560 Q_8 + 583443000 Q_8^2 + 8707129344000 Q_7^6 - 493807104000 Q_7^3 Q_8 + 3174474240000 Q_7^2 Q_8^2 + 7001316000 Q_8^3 + 28934010000 Q_8^4. \] (8.2)

In other words, regular cubics are projectively defined by constant \( c \).

### 8.2 Study extremals

Rewriting Euler equation (7.1) in terms of defining function we get the following differential equation
\[ \Phi^2 \Phi'' + \Phi \Phi'^2 - 24 \tau \Phi = 0. \]

Integrating, we get the following relation between invariants \( Q_7 \) and \( Q_8 \):
\[ Q_8^2 - (8Q_7^3 - c_1 Q_7 + c_2) = 0, \] (8.3)

which depends on two arbitrary constants \( c_1 \) and \( c_2 \).

Summarizing, we arrive at the following description of non singular cubics and Study extremals.

**Theorem 8.1.**

- Projective classes of regular cubics are defined by an arbitrary constant \( c \), where
  \[ F^3 + cGQ_7^3 = 0, \]
  and expressions for invariants \( F \) and \( G \) are given in (8.1) and (8.2).

- Projective classes of regular Study extremals are defined by relation (8.3) depending on two arbitrary constants \( c_1 \) and \( c_2 \).
